

**Abstract**—The purpose of this study was to determine if there were differences in the prevalence of musculoskeletal disorders among different types of jobs. The study included 600 employees from a large manufacturing company who had been employed by the company for at least one year. The employees were divided into three groups based on their job type: manual labor, semi-skilled work, and professional work. Data were collected through self-administered questionnaires that asked about various symptoms and signs of musculoskeletal disorders. The results showed that the prevalence of musculoskeletal disorders was highest among manual laborers, followed by semi-skilled workers, and lowest among professionals. These findings suggest that physical demands of the job are a significant factor in the development of musculoskeletal disorders.
